

HW Week 3

Max Horowitz-Gelb

February 2nd, 2017

Q1

We have shown in class that this probability can be rewritten as for arbitrary $n \geq 1$ as,

$$P(X_{n+2} = 3, X_{n+4} = 4 | X_{n+1} = 9, X_n = 8)$$

Then since X is a THMC this can be written simply as,

$$p(9, 3) * p(3, 4)^2$$

Q2

a

If $V = \max\{T, U\}$ then V is a stopping time. This is because there are only two cases.

Case 1: $T \geq U$

Since T and U are stopping times, we can check this with only $X_1 \dots X_U$, which implies then that we can tell this with only $X_1 \dots X_T$. Then in this case $V = T$ and since T is a stopping time, V can be determined with only $X_1 \dots X_V$.

Case 2: $T < U$

Since T and U are stopping times, we can check this with only $X_1 \dots X_T$ which implies we can tell this with $X_1 \dots X_U$. Then in this case $V = U$ and since U is a stopping time, V can be determined with only $X_1 \dots X_V$.

Then by definition V is a stopping time.

b

If $V = \min\{T, U\}$ then again there are the two same cases.

Case 1: $T \geq U$

Again we can tell this with only $X_1 \dots X_U$. Then $V = U$ and since U is a stopping time, we can know V with only $X_1 \dots X_V$.

Case 2: $T < U$.

Again we can determine if this inequality is true with only $X_1 \dots X_T$. And $V = T$, and since T is a stopping time, then we can determine V with only $X_1 \dots X_V$.

Therefore V is a stopping time.
